Miniquiz #6

5 Minutes

1. Consider the following grammar, which has no left recursion but is right-associative:

$$\begin{aligned}T &\rightarrow x T' \\T' &\rightarrow * x T' \\T' &\rightarrow \varepsilon\end{aligned}$$

What can you do to implement a top-down parser that constructs left-associative parse trees for the grammar above?

Option 1: First construct a right-associative concrete parse tree using the top-down parser, then rewrite the parse tree to make it left-associative.

Option 2: Have T' construct an incomplete parse tree with the leftmost child missing, and have the caller fill in the missing child (with x if the caller is T , or with a similarly incomplete subtree if the caller is also T').

2. Consider the following grammar:

$$\begin{aligned}E &\rightarrow E + T \mid T \\T &\rightarrow T * F \mid F \\F &\rightarrow (E) \mid x\end{aligned}$$

What are the first five steps of a shift-reduce parser for the input $(x * x) + x$? (Assume the parser won't take a step that would lead to an invalid string.)

- 1) SHIFT (
- 2) SHIFT x
- 3) REDUCE F
- 4) REDUCE T
- 5) SHIFT $*$
